

How to change eye color permanently?

How to change eye color permanently? Eyes play a pivotal role among the sensory organs. They are the seat of vision, the sense that is very essential in today's world. There have been lots of changes in the field of cosmetics that people change their features so that they look better than they previously were. Even the eye color is being tuned so that it suits the tastes of the person and also there are means of changing them every now and then. This has gained a lot of popularity among the people as there are lots of people who have successfully sported these methods and these have proved to be effective to them. Today, changing eye color is very common. The eye color is actually the color of the iris. So changing eye color means a change in the color of the iris. There are many methods of changing eye color. Some of the most widely used methods are using a contact lens to change the color of the eyes and also performing a surgery to change eye color. The eye color is factually the iris color. The iris is the pigmented layer of the eye and the color of this layer is visible as the cornea in front of it is a transparent membrane. The external sclera is out of consideration. Permanent eye color change is a method by which the color of the eye changes and remains in the changed color forever. This is suitable only for people who do not wish to change their eye color repeatedly. Fixing new colored iris involves intraocular implantation. This has been introduced to change the color of the eyes. Such implantations are safe, well endured and gives a distinct appearance that it looks more natural than any contact lens. This implantation is endured well because it is made of thin material called ophthalmic grade silicone. This implantation is deliberately planned to be a permanent solution that can be removed, if desired. The placing of this implantation is a simple process taking only fifteen minutes. They make use of flaps that do not reflect pressure on the corneal meshwork and the flaps assist in maintaining the position of the implant as well as allow the normal flow of aqueous. This is one of the significant reasons that many people are interested in undergoing this treatment as their eyes radiate as required for their careers. There are many who undergo this implantation for their personal preferences and have recommended good results of this surgery. Besides, people suffering from albinism also have benefited immensely. Change of color of eyes depends on various factors such as diet, sun exposure, disease and age. But people deliberately desiring to change the color of their eyes should think twice before doing so. Right now people preferring distinct colored irises have to opt for colored contacts by correcting lenses intended for vision problems or mere contact lenses only to give a distinct look. Though all these methods may sound interesting as it gives a different look and some people may even look very attractive, yet the risk factor should be considered as it may cause your vision.
